

① Exploration (human-control & intra-corporeal) ^{one-person/individual}

- Eyetracking = Design a system that can control by eyetracking
- Use electrical muscle stimulation to ~~help~~ ^{DIY} ~~exercise~~ plan
- Exoskeleton to make people have insane athletic skills and have them compete (enhanced)
e.g. exoskeleton that can help people jump further
- Use prosthetics to create an extra hand/leg for someone and make them do a specific task such as cooking or driving
- use wearables to track dancers' internal physiological data like heart rate, breathe patterns, muscles contractions, then generate corresponding training plans that are personalised based on the data to enhance dancing skills / general well-being
- A wearable where it can detect the person's sleeping cycle via their heart rate & breathing patterns & let the user know ~~the~~ whether they were having bad dreams or was it a peaceful sleep.

Strategy

high lvl
computer control

(2)

(1)

inter-corporeal
interactions

(between more than 1)

5) A basketball game based on VR glasses. People can participate the game without having a real basketball. And they can cooperate online based on matching.

1) a monopoly game where players are playing against the computer and need to win

2) a tennis match (doubles) where players are given instructions on how to win based on AI data

3) inspired by Dance Dance Revolution (the arcade game), instead of stepping on the designated dance floor, players can wear wearables and perform the same dance together, vibrations will be triggered upon wrong/unsynchronised moves

4) A collaborative hide & seek game where ~~the~~ everyone in the group will wear the wearable & the seeker can seek for their friends & the wearables will give the haptic feedback letting the seeker know if he is near his hiding friend.

③ ACTION

- inter-corporeal interactions
- high-level of computer control

Idea 1:

- A VR stimulation where surgeons wear VR glasses and immerse in same digital environment of surgery room
- They have to cooperate to conduct a typical surgery like organ transplantation
- use ~~actual~~ controllers ~~to~~ for manipulation to mimic the real situation where they have to use apparatus

~~output~~

Idea 2:-

- A group of people can wear a headset and play the same game together through headset (like black mirror)

Idea 3:

- Patients can use VR ~~headsets~~ with motion capture equipments to do rehabilitation exercise if they have muscle injury

Intra-corporal
interaction

Simulation

Idea 1

VR glasses to read books

- They can sit anywhere with their VR on & read it ~~on~~
- Or VR can also read it out to you.

Idea 2 :

for exercising app. using electrical muscle
~~on~~ simulation.

↳ Wearable devices to measure people's
bodies & APP to track data

Idea 3 :

Use haptic devices on bodies to remind
people standing up for a while

Idea 4 :

Use exoskeletons to simulate you transforming
into a different species e.g. you can only
walk like a groulla

High level
of
computer control

Idea 5 :

Winter soldier like prosthetic for people with missing
limbs that can magically understand what the amputee
wants, with little to no training; AI powered

Idea 6 :

incorporate pressure sensor on needles used for
~~acupuncture~~ acupuncture sessions, so when it detects that
certain body area / muscles are relaxed then it goes off and
notify therapist
